Kingston, New York

INTRODUCTION

The purpose of this paper is to discuss the design and development of integrated emulators for the IBM System/370. Specifically, emulation of IBM 1400 and 7000 series systems on the IBM System/370 Models 145, 155 and 165, integrated under an Operating System. While the author acknowledges the development and presence of emulation outside of IBM, it is not the intent of this article to conduct a comparative survey of all emulator products. Rather, the discussion will be restricted to the design and development considerations involved in producing the System/370 integrated emulators.

EMULATOR HISTORY

The System/370 integrated emulators are evolutionary products of earlier IBM emulators on System/360. Before discussing the design and functional characteristics of the System/370 emulators, a review of emulation as it existed prior to System/370 is presented in order to form a base of comparison for the new system.

Three methods are employed by the emulators to effect the execution of prior systems programs on the new system and are referred to throughout this article:

1. Interpretation/execution via hardware (referred to as emulation).
2. Interpretation/execution via software routine (referred to as simulation).
3. A combination of the above (referred to as emulation).

In System/360, emulation was composed of three distinct design types:

1. Hardware: Some emulators, such as the IBM 1401 emulator on System/360 Model 30, were exclusively implemented by hardware. The Model 30 became, in effect, a 1401, with the appropriate registers, addressing, I and E-time execution, etc., handled by the hardware. While performance and operating characteristics were quite good, the system was dedicated to a specific mode of operation, i.e., either emulation or "native" mode. The resultant loading and reloading necessary to attain the desired mode of operation imposed unproductive overhead on the user.

2. Hardware/Software: Other emulators, such as the IBM 7000 series emulators on System/360 Model 65, were comprised of both hardware and software. By adding software, the emulator offered more flexibility in device support and operational characteristics, while at the same time retained the desirable performance attributes of hardware execution. (Pure software implementation would become total simulation, with the obvious degradation of performance.) These emulators required a total dedication to the system of a specific operating mode—emulation or native, with the unproductive overhead of loading and reloading. This overhead was more noticeable when the native mode operation involved an operating system. Additionally, terminal applications were not possible because of the necessity to "shut down" the operating system for emulator loading.

3. Hardware/Software/Operating System: Two programs, Compatibility Operating System (COS)/30 and COS/40 were developed by IBM which integrated the 1401 emulator on System/360 Models 30 and 40 under DOS. At first considered to be interim programs, these programs, because of their wide acceptance and usage, were subsequently upgraded through hardware and software refinements and renamed Compati-
ility System (CS)/30 and CS/40. For the first
time, 1401 jobs and System/360 native-mode
jobs could be run concurrently in a limited multi-
programming environment. (Limited multipro-
gramming in the sense that there were certain
restrictions on the Foreground/Background allo-
cation of jobs under DOS.) Single job stream
input was also possible. Overall system thruput
was significantly improved by eliminating the
need to reload the system between emulator and
System/360 jobs.

In addition to the CS emulators, there were other
applications such as Hypervisors and “hook loaders,”
which, to a lesser degree, provided a single operating
environment by eliminating the need to re-IPL be-
tween emulator and System/360 jobs. Hypervisors en-
abled two emulators to run concurrently or, an emu-
lator to run with a System/360 job.

The Hypervisor concept was relatively simple. It con-
sisted of an addendum to the emulator program and a
hardware modification on a Model 65 having a com-
patibility feature. The hardware modification divided
the Model 65 into two partitions, each addressable from
0-n. The program addendum, having overlaid the sys-
tem Program Status Words (PSW) with its own, be-
came the interrupt handler for the entire system. After
determining which partition had initiated the event
causing the interrupt, control was transferred accord-
ingly. The Hypervisor required dedicated I/O devices
for each partition and, because of this, the I/O con-
figurations were usually quite large, and, therefore,
prohibitive to the majority of users.

Hook loaders, developed by individual installations,
effectively a “roll-in/roll-out” of the emulator or System/
360 job. The decision to swap operating modes could
be interrupt driven or initiated by the operator. The
basic attribute of this application was to eliminate the
need for IPL when changing operating modes.

DESIGN CONSIDERATIONS AND
OBJECTIVES

At the time they were initially released, the System/
360 emulators were considered to be short term pro-
grams. They were intended to provide the user with
the facility to grow from a second generation system
to the improved facilities of System/360 with little or
no reprogramming. To this end, they served their pur-
pose very well. Their predicted demise however, did
not take place as expected. Emulation usage continued
at a high rate, with installation resources directed at
new applications rather than conversion of existing
applications.

Clearly, as system and customer applications became
more complex, the need for expanded emulator support
became more evident. Early in the planning cycle of
System/370, IBM began a design study to determine
the most efficient architecture for emulators on Sys-
tem/370. Based on an analysis of existing and projected
future operating environments, feedback from user
groups, and the experience gained to date with emula-
tion, the following key design points were established
as objectives for System/370 emulators:

1. Emulators must be fully integrated with the
operating system and run as a problem program.
2. Complete multiprogramming facilities must be
available including multiprogramming of
emulators.
3. Device independence, with all device allocation
performed by the operating system.
4. Data compatibility with the operating system.
5. A single jobstream environment.
6. A common, modular architecture for improved
maintenance and portability.
7. An improved hardware feature design with emu-
lator mode restrictions eliminated and all feature
operations interruptible.

MODELING

While the COS/CS emulators had proved the basic
feasibility of integrating an emulator as a problem pro-
gram under an operating system, in this case DOS,
extending this feasibility to include a large scale, com-
plex system with the full multiprogramming facilities
of OS/360 remained to be proven. Therefore, it was
decided that a model should be built which would inte-
grate a large scale system into OS/360.

The system selected was the 7094 Emulator on Sys-
tem/360 Model 65. The 7094 and the 7094 Operating
System (IBSYS) represented the most complex and
sophisticated second generation system available. If
this system could be successfully integrated with OS/
360, the design and technology could certainly be ap-
plied to smaller, less complex systems.

The OS/360 option selected was MFT II. This sys-
tem, with its fixed partition requirement, could be more
easily adapted to the 7094 Emulator design which also
included fixed locations and addressing.

This particular feasibility study proved to be an ex-
cellent subject for modeling. The goals were well de-
defined, the emulator itself was relatively self contained,
and the design alternatives were varied enough to make
Multiple design evaluations necessary. Modeling was primarily concerned with the assessment of four major areas: input/output techniques, operation under an operating system, hardware design/requirements, and operating system interfaces. There were a number of key recommendations and resolutions achieved in these areas as the result of modeling.

**Input/output techniques**

- To provide the most efficient means of I/O Simulation, an emulator access method with standard interfaces to the operating system was developed. OS/360 Basic Sequential Access Method (BSAM) was used for tape operations and Queued Sequential Access Method (QSAM) for support of Unit Record devices. Basic Direct Access Method (BDAM) support was later added for those systems that support disk. This access method was subsequently expanded to be usable by any System/370 emulator, regardless of the emulated system. This access method is currently used by the 1400 and 7000 series emulators on System/370.
- To solve the problem of prohibitively long tape records (32K maximum), and some file formats which were unacceptable to OS/360, a tape preprocessor program was developed to format second-generation tapes into a spanned variable length record format. A post-processor was also developed to convert these tapes back to their original format, if desired.
- To enable selective processing for Operating System error recovery procedures, parity switching and density switching modifications were made to the data management facilities of OS/360.

**Operation under an operating system**

- Whereas the stand alone emulators had used privileged instructions at will, this could not be done if the emulator was to run as a problem program under the operating system. Those routines requiring privileged Op-Codes were either replaced by operating system routines or redesigned to use only standard Op-Codes.
- To achieve a common, portable architecture, emulator routines were standardized as emulator dependent and operating system dependent modules.

**Hardware design/requirements**

The need to operate in emulator mode should be eliminated. The emulator program should be transparent to the operating system.

**Operating system interfaces**

- There should be no fixed addresses and the emulator including the target memory, should be relocatable.
- Emulator Op-Codes should be standardized.
- Emulator Op-Codes should be interruptible and capable of retry. (In emulation, it is possible to remain in E-time simulation for an unusually long period of time, relative to normal System/370 E-time. Therefore, the hardware feature, must be fully interruptible if functions requiring the immediate dispatch of asynchronous interrupts are to be supported.)
- Hardware/Software communication should be done via General Purpose Registers and Floating Point Registers rather than through special hardware registers and/or fixed tables. This is required if emulators are to be multiprogrammed.

**Models**

These systems represent the most advanced emulators ever offered in the IBM product line, combining the powerful new System/370, its high performance I/O devices, the multiprogramming facilities of Operating System (OS)/360 and Disk Operating System (DOS)/360, and an improved technology in emulator design.

SYSTEM REQUIREMENTS AND FEATURES

On the Model 155 there are four emulator combinations available. The 1401/1440/1460 Emulator under both DOS and OS and the 1410/7010 Emulators under DOS and OS. These are four separate programs, each with an individual program number. The compatibility feature on System/370 Model 155 is an integrated feature which provides the facility to emulate the 1401/1440/1460/ and 1410/7010. These emulators can be multiprogrammed in any combination.

On the model 165—7074, 7080 and 7094 emulators are provided. These emulators run under OS/360 and can be multiprogrammed. Each emulator consists of a compatibility feature and a corresponding emulator program that has a unique feature and program number. Only one feature can be installed in the system at one time.

The System/370 emulators have a number of requirements, considerations and support functions in common:

Minimum Requirements
- Compatibility Feature
- A sufficient number of System/370 I/O devices to correspond to the devices on the system being emulated, plus the devices required by the Operating System.
- Sufficient System/370 processor storage for: (1) the version of the operating system being used (MFT, MVT or DOS), (2) emulator functions needed for the system being emulated, and (3) the program being executed.

Additional Features
- Two tape formatting programs are provided: (1) to convert 1400/7000 series tape files to Operating System (spanned variable length) format for more efficient data handling by the emulator, and, (2) to convert output records in spanned variable length format to original 1400/7000 series format.
- A disk formatting program is provided to assist in converting 1400/7010 disk files to the standard Operating System format.

Data File Restrictions:
- 1400/7000 series tape files must be converted if record lengths exceed 32,755 bytes or, if data is in mixed densities.
- All 1400/7010 disk files must be converted.

COMPATIBILITY FEATURES

The Compatibility Features on System/370 Models 155 and 165 are under microprogram control. The feature on the Model 155 is an installed resident feature, whereas on the Model 165 it is loaded into “Writable Control Storage” via the console file.

The compatibility feature is, in effect, a number of special instructions added to the base System/370. These special instructions are used by the emulator program to emulate target machine operations. The selection of operations to be performed by the special instructions is based on an analysis of the target machine operations relative to complexity and frequency of use.

The most significant special instruction (since it is used once for each target machine instruction executed) is called DO INTERPRETIVE LOOP or simply, DIL (Figure 1). The DIL instruction replaces with a single instruction the subroutine that a pure software sub-
routine would use to:

1. Access the simulated instruction counter (IC).
2. Convert the IC to a System/370 address in the simulated target machine storage which contains the instruction to be interpreted.
3. Fetch the instruction.
4. Update and restore the simulated IC.
5. Perform any indexing required for the subject instruction.
6. Convert the effective address obtained to the System/370 address in the simulated target machine storage which contains the subject operand.
7. Interpret the instruction Op-Code and branch to the appropriate simulator routine which will simulate the instruction.

INPUT/OUTPUT DEVICE CORRESPONDENCE

Expanded support of I/O devices is provided with the System/370 integrated emulators. The OS Emulators employ the QSAM, BSAM and BDAM facilities of OS/360 Data Management, and offer device independence within the support capabilities of these access methods. The DOS emulators provide device independence only for Unit Record devices.

DISTRIBUTION

DOS

The DOS emulators for 1400/7010 are distributed as components of DOS. Standard DOS system generation procedures are followed in generating an emulator system.

OS

The OS emulators for System/370 Models 155 and 165 are distributed independently of OS/360. Independent distribution was chosen inasmuch as the emulator modules would be superfluous to System/360 users and take up unnecessary space on the distributed system libraries.

SUPPLEMENTAL PROGRAMS

Tape formatting programs

Two tape formatting programs are distributed with the emulator program. The Preprocessor program converts tapes in original 1400/7000 series format to spanned variable-length record format. Any 1400/7000 series tape containing records longer than 32,755 characters must be preprocessed. Preprocessing of other tapes is optional, although greater buffering efficiency can be obtained because the emulator is intended to normally operate with a spanned variable-length format.

The post-processor program converts tape data sets from spanned variable-length format to 1400/7000 series format. The programs support tapes at 200, 556, 800 and 1600 BPI density and handle mixed density tapes. The programs support even, odd and mixed parity tapes.

Disk formatting program

A disk formatting program is provided to assist in converting 1400 disk files to a format acceptable to the emulator program. The disk formatting program runs as a problem program under the operating system. The program creates a data set composed of control information and of blank records whose size and number are determined by the device being emulated.

COMMUNICATING WITH THE EMULATOR PROGRAM

A full range of operator services are provided for operator communication with the emulator program. 1400/7000 series console operations are simulated through commands entered by the operator.

In an integrated, multiprogramming environment, the operating characteristics are expected to initially be more difficult for the operator. However, every effort has been made to ease the transition from stand-alone to integrated operation. Messages from the emulator program are identified by a unique message ID, including a sequentially.incremented message number and the job name of the program being emulated. The user has the option of including multiple console support and directing emulation messages to the second console.

SUMMARY

The System/370 integrated emulators have significantly extended the technology of emulation. They bring to the user an improved, more efficient operating environment for emulator and native mode System/370 jobs, while at the same time providing a nondisruptive growth path for today’s System/360 user.
